

AI for Mathematics — Group Project Presentation

PRESENTATION TITLE GOES HERE

Group N — Tuesday 7 July 2026, 15:00–18:00, A4#G11 — XMUM General Elective

Group members: Student A; Student B; Student C

Department of Mathematics and Applied Mathematics,
Xiamen University Malaysia.

(Optional group photo or
project diagram)

Project topic: One-sentence topic assigned by the instructor.

Contact: group-lead-email@example.com

ABSTRACT

Write 150–200 words. State: (1) the project question, (2) the method or workflow, (3) the preliminary results, and (4) what a reader should take away from the poster.

QUESTION AND MOTIVATION

What did the project study? Why does this small question matter for AI-for-mathematics? Which course ideas or papers does it build on? Keep this section focused — one paragraph and, if useful, a small figure or citation list.

METHOD / WORKFLOW

Describe the workflow, tool chain, prompt design, dataset, or theorem set. If possible, include a diagram of the pipeline so a reader can see the loop between LLM output, checking, and repair. State explicitly what counts as one “trial” and how success or failure is decided.

PRELIMINARY RESULTS

Report what actually happened. Use a table, a small chart, or 1–2 representative examples. Preliminary results should be honest: report the number of trials, the success rate, and the failure count. Do not overclaim.

REPRESENTATIVE EXAMPLE

Walk through one concrete example end-to-end: the input, one or two steps of the workflow, and the final output. Choose an example that shows the method working AND, if space allows, one example where it fails. Concrete examples are usually the most persuasive part of a poster.

ERROR ANALYSIS AND LIMITATIONS

What were the main failure modes? What should a reader NOT conclude from this poster? For instance: small task set, no held-out test data, single random seed, only one LLM tested, no comparison with a strong baseline, etc. This section is required.

AI USE STATEMENT

Which AI tools were used (Claude, ChatGPT, Copilot, llmlean, Lean-aware agents, etc.)? For which tasks (coding, drafting, proof attempts, literature search, slide preparation)? How were the outputs checked (Lean type check, code tests, manual proof review, source verification)?

REFERENCES

List the key papers, Mathlib pages, documentation, datasets, and software that the project relies on. Keep the list short and specific — 6–10 items is enough for a poster.
